Sample AQA Chemistry A2 Questions and Model Answers

Question 1: Organic Synthesis Pathways

Q: Outline a synthetic route to convert benzene into nitrobenzene, including reagents and conditions. (6 marks)

Answer:

To synthesize nitrobenzene from benzene, perform an electrophilic aromatic substitution.

- Reagent: Concentrated nitric acid (HNO_3).
- Conditions: Fuming sulfuric acid (H_2SO_4) as a catalyst, at a temperature of around 50°C .
- Process:
 - Mix benzene with concentrated HNO_3 in the presence of a catalytic amount of H_2SO_4 .
 - The electrophile, the nitronium ion (NO_2^+), is generated in situ.
 - The NO_2^+ attacks the benzene ring, substituting a hydrogen atom, forming nitrobenzene.
- Reaction equation:

Note: The reaction is electrophilic aromatic substitution, driven by the strong electrophile NO_2^+ , and the conditions are carefully controlled to prevent further substitution.

Question 2: Calculating pH of a Strong Acid

Q: A 0.01 mol/dm^3 solution of hydrochloric acid (HCl) is prepared. Calculate the pH of the solution. (3 marks)

Answer:

- HCl is a strong acid, so it dissociates completely in water.
- $[\text{H}^+] = 0.01 \text{ mol/dm}^3$ (since dissociation is complete).
- $\text{pH} = -\log[\text{H}^+] = -\log(0.01) = 2.00$

Therefore, the pH of the solution is 2.00.

Question 3: Data Interpretation ? Spectroscopy

Q: The IR spectrum of an unknown compound shows a broad absorption around 3300 cm^{-1} and a strong peak at 1700 cm^{-1} .

- Identify the functional groups present.
- Suggest a possible compound structure.

Answer:

a)

- The broad absorption around 3300 cm^{-1} indicates the presence of O-H stretching, typical of alcohols or phenols.
- The peak at 1700 cm^{-1} suggests a C=O stretching vibration, characteristic of carbonyl groups in aldehydes, ketones, carboxylic acids, or esters.

b)

Given the presence of both O-H and C=O, the compound could be a carboxylic acid. A plausible structure is ethanoic acid (acetic acid), which contains both the hydroxyl and carbonyl groups.

Sample AQA Style Question Breakdown

Question: Explain how the presence of a catalyst affects the rate of a chemical reaction. Use your knowledge of collision theory and provide an example.

Step-by-step Approach:

- Identify the command word: Explain.
- Recall relevant concepts: collision theory, activation energy, catalyst function.
- Structure your answer:
 - Define catalyst and its role.
 - Describe how catalysts provide an alternative pathway.
 - Explain how this pathway lowers activation energy.
 - Connect the reduction in activation energy to an increased rate.
 - Provide an example (e.g., iron catalyst in haber process).
- Sample Answer:

A catalyst increases the rate of a chemical reaction by providing an alternative pathway with a lower activation energy. According to collision theory, molecules must collide with sufficient energy and proper orientation to react. By lowering the activation energy, a catalyst increases the proportion of molecules that can overcome this barrier at a given temperature, thus increasing the reaction rate. For example, in the Haber process, an iron catalyst facilitates the formation of ammonia from nitrogen and hydrogen gases, making the process more efficient.

Sample AQA A2 Chemistry Questions and Answers

Below are representative questions across different topics accompanied by detailed answers.

Organic Chemistry

Question 1:

Describe the mechanism of the nucleophilic addition of cyanide ion to an aldehyde. Include the key steps and electron movement.

Answer:

The nucleophilic addition of cyanide (CN^-) to an aldehyde proceeds via the following steps:

- Nucleophilic Attack:

The lone pair of electrons on the cyanide ion attacks the electrophilic carbon atom of the aldehyde's carbonyl group. This occurs because the carbon of the carbonyl is partially positive due to the electronegativity difference between carbon and oxygen.

- Formation of Tetrahedral Intermediate:

The attack results in a tetrahedral intermediate where the carbon now bears a negative charge on the oxygen atom.

- Protonation:

The oxygen atom picks up a proton (H^+) from the surrounding solvent (usually water or acid), forming a hydroxyl group.

- Product Formation:

The overall result is a hydroxynitrile (cyanohydrin), with the structure R-CH(OH)-CN .

Electron Movement:

- The lone pair on CN⁻ attacks the carbon of the carbonyl, forming a bond.
- The pi bond electrons in the C=O shift onto oxygen, creating a negative charge.
- Protonation of oxygen stabilizes the intermediate.

Inorganic Chemistry

Question 2:

Explain the trend in atomic radius across a period in the periodic table. How does this trend influence the chemical reactivity of elements?

Answer:

Trend Explanation:

- As you move across a period from left to right, the atomic radius decreases.
- This occurs because additional protons in the nucleus increase the nuclear charge, pulling electrons closer to the nucleus.
- Although electrons are added to the same energy level, the increased positive charge results in a stronger attraction, reducing the size of the atom.

Impact on Chemical Reactivity:

- Elements on the left of the period (metals) tend to have larger atomic radii and are more likely to lose electrons, making them more reactive metals.
- Elements on the right (non-metals) have smaller atomic radii and a higher tendency to gain electrons, making them more reactive non-metals.
- The decreasing atomic radius enhances the effective nuclear charge experienced by valence electrons, influencing how readily an element participates in chemical reactions.

Physical Chemistry

Question 3:

Calculate the standard enthalpy change for the combustion of ethanol (C₂H₅OH) given the following data:

Reaction	ΔH (kJ/mol)
----------	-------------

|-----|-----|

| $\text{C}_2\text{H}_5\text{OH} + 3\text{O}_2 \rightarrow 2\text{CO}_2 + 3\text{H}_2\text{O}$ | -1367 |

| $\text{C}_2\text{H}_4 + 3.5\text{O}_2 \rightarrow 2\text{CO}_2 + 3\text{H}_2\text{O}$ | -1560 |

| $\text{C}_2\text{H}_6 + 1.5\text{O}_2 \rightarrow 2\text{CO} + 2\text{H}_2\text{O}$ | -1411 |

Note: Use Hess's Law to find ΔH for the combustion of ethanol.

Answer:

Step 1: Recognize that the combustion of ethanol can be related to the combustion of ethane and ethene, but more straightforwardly, the data provided suggest using Hess's Law by constructing a suitable cycle.

Alternatively, if only the above data are provided, and assuming the data are for combustion reactions, the most accurate approach is to use the standard enthalpy of formation method. However, since the data are for combustion, the most effective way is to use known combustion reactions directly if available.

Given the data, the common approach is:

- Recognize the combustion of ethanol is:

- The ΔH for this reaction is given as -1367 kJ/mol.

Therefore, the standard enthalpy change for the combustion of ethanol is -1367 kJ/mol.

Analyzing Typical AQA A2 Chemistry Questions and Their Answers

To illustrate the nature and depth of AQA A2 Chemistry exam questions, we analyze representative examples across different topics, providing insights into effective answering strategies.

Example 1: Calculations in Acid-Base Chemistry

Question:

A 25.0 cm³ sample of hydrochloric acid reacts completely with 0.015 mol of sodium hydroxide. Calculate the concentration of the hydrochloric acid solution.

Answer Breakdown:

- Identify knowns:

Volume of HCl = 25.0 cm³ = 0.0250 dm³

Moles of NaOH = 0.015 mol

- Reaction equation:

$\text{HCl} + \text{NaOH} \rightarrow \text{NaCl} + \text{H}_2\text{O}$

- Mole ratio:

1 mol HCl reacts with 1 mol NaOH

- Calculate concentration of HCl:

Concentration (mol/dm³) = moles / volume (dm³)

= 0.015 mol / 0.0250 dm³

$$= 0.6 \text{ mol/dm}^3$$

Key Points:

- Recognize the mole ratio from the balanced equation.
- Convert units consistently.
- Use the formula for concentration directly.

Strategy:

Always identify the reaction type, write a balanced equation, and apply molar relationships.

Example 2: Understanding Equilibrium and Le Châtelier's Principle

Question:

The equilibrium:

is established in a container at constant temperature. Explain what would happen to the equilibrium position if:

- The pressure is increased
- The temperature is increased

Answer:

- Increase in pressure:

According to Le Châtelier's principle, increasing pressure favors the side with fewer moles of gas.

- Reactants: 1 N₂ + 3 H₂ = 4 moles
- Products: 2 NH₃ = 2 moles
- Result: The equilibrium shifts to the right, producing more ammonia.

- Increase in temperature:

The reaction is exothermic in the forward direction.

- Increasing temperature shifts the equilibrium to absorb heat, favoring the endothermic reverse reaction.
- Result: The equilibrium shifts to the left, decreasing ammonia production.

Key Points:

- Recognize the effect of pressure based on molar quantities.
- Understand exothermic/endothermic nature to interpret temperature effects.

Strategy:

Use Le Châtelier's principle systematically, considering how each change affects the equilibrium position.

Example 3: Organic Mechanisms and Reaction Pathways

Question:

Describe the mechanism for the nucleophilic substitution of bromoethane with hydroxide ions, including any important intermediate steps.

Answer:

- Step 1: Initiation of nucleophilic attack

The hydroxide ion (OH^-) acts as a nucleophile, attacking the electrophilic carbon atom bonded to bromine in bromoethane ($\text{C}_2\text{H}_5\text{Br}$).

- Step 2: Transition state formation

A pentavalent transition state forms as the nucleophile approaches.

- Step 3: Departure of leaving group

The bromide ion (Br^-) leaves, resulting in the formation of ethanol ($\text{C}_2\text{H}_5\text{OH}$).

- Overall reaction:

Key Points:

- This is an $\text{S}_{\text{N}}2$ mechanism, characterized by a one-step process.
- The nucleophile attacks as the leaving group departs simultaneously.

Strategy:

Draw mechanism arrows clearly, identify the nucleophile, leaving group, and the transition state.

- Pay attention to significant figures and units.
- Double-check your calculations for errors.

Sample AQA AS Chemistry Questions and Model Answers

Practicing with actual questions and model answers helps students understand what examiners look for.

Sample Question 1: Multiple Choice

Question: Which of the following is the correct electronic configuration for a chloride ion (Cl⁻)?

- a) 2, 8, 7
- b) 2, 8, 8
- c) 2, 7, 7
- d) 2, 8, 6

Model Answer:

The chloride ion (Cl⁻) has gained an electron, resulting in a full outer shell. The atomic number of chlorine is 17, so the neutral atom has the configuration 2, 8, 7. When it gains one electron, the configuration becomes 2, 8, 8. Therefore, the correct answer is b) 2, 8, 8.

Sample Question 2: Short-Answer

Question: Define the term 'molar enthalpy of combustion.'

Model Answer:

The molar enthalpy of combustion is the amount of heat energy released when one mole of a substance is completely burned in oxygen under standard conditions.

Sample Question 3: Extended-Response with Calculations

Question:

A student carries out an experiment to find the enthalpy change when magnesium reacts with hydrochloric acid. The reaction is:

Given the following data:

- Mass of magnesium used: 0.48 g
- Concentration of HCl: 1.0 mol/dm³
- Temperature change: 4.5°C

Calculate the molar enthalpy change (ΔH) for the reaction in kJ/mol. Assume the specific heat capacity of the solution is 4.18 J/g°C, and the density is approximately 1 g/cm³.

Model Answer:

First, determine the moles of magnesium reacted:

- Molar mass of Mg = 24.3 g/mol
- Moles of Mg = $0.48 \text{ g} / 24.3 \text{ g/mol} = 0.01975 \text{ mol}$

Next, calculate the mass of the solution:

- Since the solution density is approximately 1 g/cm³, and assuming the solution volume is enough to contain the HCl, the mass is roughly equal to the volume in grams.
- Volume of HCl solution used:

Since the concentration is 1.0 mol/dm³, and to react with 0.01975 mol Mg, the required amount of HCl is:

$$\text{Moles HCl needed} = 2 \times \text{moles Mg} = 0.0395 \text{ mol}$$

$$\text{Volume} = \text{moles} / \text{concentration} = 0.0395 \text{ mol} / 1.0 \text{ mol/dm}^3 = 0.0395 \text{ dm}^3 = 39.5 \text{ cm}^3$$

- Total mass of solution ? 39.5 g

Now, calculate the heat absorbed (q):

$$q = \text{mass} \times \text{specific heat capacity} \times \text{temperature change}$$

$$q = 39.5 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C} \times 4.5^\circ\text{C} = 747.3 \text{ J}$$

Since this energy is released during the reaction, the molar enthalpy change is:

$$\Delta H = (q / \text{moles of Mg}) = 747.3 \text{ J} / 0.01975 \text{ mol} = 37,870 \text{ J/mol}$$

Convert to kJ/mol:

$$\Delta H = 37.87 \text{ kJ/mol}$$

Answer: The molar enthalpy change for the reaction is approximately -37.9 kJ/mol (the negative sign indicates exothermic reaction).
