Sample Questions and Detailed Explanations from OCR Chemistry May 2013 F321

Below are typical questions from the exam along with comprehensive explanations to aid understanding.

Question 1: Nucleophilic Substitution in Halogenoalkanes

Question:

Explain why bromoethane reacts more slowly with aqueous potassium hydroxide than chloroethane. Include in your answer the factors affecting the rate of nucleophilic substitution.

Answer Explanation:

The rate of nucleophilic substitution in halogenoalkanes depends on the strength of the carbon-halogen bond and the ability of the halogen to leave as a leaving group.

- Bond Strength: The C-Br bond in bromoethane is weaker than the C-Cl bond in chloroethane because bromine is larger and less tightly held, making the bond easier to break.
- Leaving Group Ability: Bromide ions (Br^-) are better leaving groups than chloride ions (Cl^-) due to their larger size and greater polarizability, which stabilizes the negative charge once they leave.
- Reaction Rate: Since bromine's bond is weaker and its leaving group is more stable, bromoethane reacts more rapidly in nucleophilic substitution reactions compared to chloroethane.

Key Point: The combination of bond strength and the stability of the leaving group influences the rate; thus, bromoethane reacts faster than chloroethane under similar conditions.

Question 2: Aromatic Substitution

Question:

Describe the electrophilic substitution of benzene with a nitrating mixture and explain why benzene reacts more slowly than alkene with electrophiles.

Answer Explanation:

- Reaction Conditions: Benzene reacts with a mixture of concentrated nitric acid and sulfuric acid (the nitrating mixture) in the presence of a catalyst (H_2SO_4).
- Reaction Mechanism: The electrophile generated is the nitronium ion (NO_2^+). Benzene undergoes substitution, not addition, preserving its aromatic ring.
- Reaction Rate: Benzene reacts more slowly than alkenes because of its aromatic stability. The

delocalized π -electron system in benzene is highly stable, and disrupting this stability requires significant energy. Therefore, electrophilic substitution occurs at a slower rate compared to the addition reactions of alkenes, which lose some of their π -bond character but are less stabilized overall.

Key Point: Aromaticity confers extra stability to benzene, which resists addition reactions, favoring substitution that preserves the aromatic system.

 - Example: Confusing "ionic bond" with "covalent bond."
 - Solution: Memorize definitions and practice applying terms in context.
- Incomplete Explanations
 - Example: Stating "reduction is gain of electrons" without explaining its effect on oxidation state.
 - Solution: Provide full explanations with relevant examples.
- Misreading Data or Graphs
 - Example: Interpreting a trend incorrectly.

- Solution: Practice data interpretation and confirm your understanding before drawing conclusions.

- Calculation Errors

- Example: Incorrect units or arithmetic mistakes.

- Solution: Double-check calculations and ensure units are consistent.

Sample Breakdown: Analyzing a Typical June 2013 Question

Suppose a question asks: "Explain why metals are good conductors of electricity."

Mark Scheme Breakdown:

- Key points to include:

- Metals have free electrons (delocalized electrons).

- These electrons can move freely throughout the metal lattice.

- Movement of electrons allows electrical current to flow.

Scoring Guide:

- Full marks: Mention the presence of free/delocalized electrons and their role in conducting electricity.

- Partial marks: Mention electrons but omit their delocalized nature or the reason for conduction.

- Common errors: Confusing electrons with ions or neglecting the role of electrons altogether.
